PURPOSE: This book is intended for petroleum specialists of scientific research establishments, educational institutions, and petroleum refining plants.
DESCRIPTION: This collection is the first of a multivolume publication on the results of scientific research work carried out in the Soviet Union on the chemistry and technology of sulfur- and nitrogen-organic compounds during the period 1974-1985; and according to a coordinated research project outlined in 1976 by the sponsoring agency (Bashkir Branch, AN SSSR).

Myts, S. I. (Institut organicheskoy khimii AN SSSR—Institute of Organic Chemistry, AN SSSR). Synthesis of Compounds of the Aliphatic Series on the Basis of Thiophene and Its Homologs.
The author states that tar from Povolzh'ye (Volga region) shales and sulfurous petroleum may serve as innumerable sources of thiophene and its homologs. Reaction diagrams are given for the synthesis of aliphatic compounds from this material, which yielded α -hydrocarbons, higher alcohols, glycols, acids, oxy-acids, α , β , γ - and other enone acids, enone dicarboxylic acids, tertiary amines, amine alcohols, simple esters, etc.

TITLE: An Apparatus for Determining the Melting Temperature (Pribor dlya opredeleniya temperatury plavleniya)

PERIODICAL: Zavodskaya Laboratoriya, 1958, Vol 24, Nr 10, pp 1279-1281 (USSR)

ABSTRACT: The existing apparatus for determining the melting temperature have a number of deficiencies caused by unequal heating (Ref 1), a complicated construction (Refs 2-4), and by the danger existing in determinations at higher temperatures. The systems known from publications using metallic monolite blocks (Refs 5,6) are also imperfect. The apparatus described in this paper makes possible a determination of the melting temperature from 20° to 500°, and it is possible to investigate several samples of organic and inorganic substances at the same time. The heating velocity can be regulated from 0,2 to 10 degrees/minute. A figure and a schematic representation of the apparatus are given. From the description it may be seen that a measuring microscope of the type МПБ-2 with a 24-fold magnification is used. The sample is illuminated at an acute angle and after melting can also be observed in the transmitted light from a second light source. There are 2 figures and 6 references.

① *The Factors Causing the Formation of Fissures in Coke.*
E. M. Taits. (*Doklady Akademii Nauk S.S.R.*, 1953, 12, (6), 1025-1027). [In Russian]. The mechanism of the formation of fissures in coke which are caused by the development of internal stresses appearing as a result of processes accompanying the process of shrinking is discussed. Internal stresses, appearing in coke and producing fissures are determined by two parameters, i.e., the gradient of shrinkage μ and the cohesive force between two adjacent layers (N). The parameter μ is determined by the dynamics of breakdown of the coking material, the latter being dependent on the absolute value of shrinkage and the rate of heating the coking mixture. The parameter N is determined by the coking properties of the coal, i.e., by its viscosity in the plastic state, and depends on particle size, contents of mineral admixtures, degree of compression, on some other factors. - v. u.

Factors causing the formation of cracks in coke. P. M. Tait
(*Izdat. Akad. Nauk SSSR*, 1953, **93**, 1077-1079). One of the prime causes of shrinkage of coke in a coke oven is the change of shrinkage on passing through the bed from the centre (of a horizontal furnace) to the outside walls, since this sets up stresses in the mass which exceed its tensile or compressive strength; the other is the degree of adhesion between contiguous layers.

Translation from: Referativnyy zhurnal, Geologiya, 1957, Nr 4,
p 143 (USSR)

AUTHOR: Tayts, Ye. M.

TITLE: Change in Hardness of Coal During Metamorphism and
Under Thermal Treatment (Izmeneniye prochnosti ugley
v protsesse metamorfizma i pri termicheskoy obrabotke)

PERIODICAL: Tr. Labor. geol. uglya AN SSSR, 1956, Nr 6, pp 156-
163

ABSTRACT: Tests of the hardness of coal were conducted. D
quality coal has a very low hardness; gas producing
coal has a high hardness. PZh and K quality coal
have the least hardness. Hardness increases in
medium-grade coal, and reaches its maximum in anthra-
cites. Sapropelites have a very low hardness (10 to
11 kg/sq mm). Abrasion tests conducted in a drum
with emery paper showed that abrasion varies, and

Card 1/3

15-57-4-5066

Change in Hardness of Coal (Cont.)

that it reaches a maximum in coal of an average degree of metamorphism. The abrasional resistance of anthracite, determined under various test conditions, was either higher or lower than the abrasional resistance of long-flame coal. The hardness and abrasional resistance of dull coal are lower than those of lustrous coal. A special apparatus was used to test elastic properties. Laminae cut from the coal parallel to the stratification were tested for bending. The amount of deformation is a straight-line function of load. This relationship does not hold in the last moment before failure. As a rule, lustrous coal has greater elasticity than dull coal. The modulus of elasticity decreases with an increase in degree of metamorphism. Specimens were heated in a tubular furnace at a rate of 8° C per minute to determine the degree of change in hardness of medium-grade coal as a result of heating it without air access. This coal increases in hardness as a result of heating. The increase is greater for coal of a low degree of metamorphism than for highly metamorphosed coal. The density and hardness of

Card 2/3

15-57-4-5066

· Change in Hardness of Coal (Cont.)

· coal change slightly with temperature up to 550° C and increase markedly with a further increase in temperature. Crushing strength increases sharply with temperature up to 550° C and then decreases to a minimum at a temperature of 750° C; it increases again slightly beyond this point. Heating of coal, like metamorphism under natural conditions, produces a structural change. This change consists in increase in the size of the elementary carbon lattice.

TITLE: The Process of Formation and Forecasting of Coke Quality
(Protsess obrazcavaniya i prognoz kachestva koksa)

PERIODICAL: Koks i Khimiya, 1958, Nr 3, pp 19-25 (USSR).

ABSTRACT: Factors influencing the strength of coke material, fissuring of coke, and the strength of lump coke are discussed. On the basis of theoretical considerations an equation is proposed which relates the quality of coke and viscosity of the plastic mass of coal and shrinkage gradient (Eq.(4)). As the data required for the solution are not known, a simplified equation is proposed, relating coke quality through a coefficient with the coking ability and shrinkage of coal on coking (i.e., parameters of the coking ability of coal). Using available data on a number of coal blends (Table 2) a plot of coke quality versus coking ability of coal is made which gives a straight line. Thus, on the basis of simple laboratory tests, the quality of coke produced can be forecast. There are 2 tables, 1 figure and 13 Soviet references.

TITLE: The Evaluation of the Plasticity of Coals on Heating
(Otsenka plastichnosti kamennykh ugley pri nagreve)

PERIODICAL: Koks i Khimiya, 1958, Nr 7, pp 11-14 (USSR)

ABSTRACT: A new method of evaluating the plasticity of coal on heating based on measuring the stress required to draw a steel ball through a plastic coal mass with a constant velocity. The apparatus (Fig.1) and the experimental procedure are outlined. A curve characterising plastic properties of coal (Fig.2a) is obtained by plotting stress versus temperature or time. The shape of this curve is compared with four other curves characterising plastic properties of coals, obtained by other methods and their general similarity is stressed. From the minimum stress required to draw the ball through heated samples of various types of coal the author calculated the minimum apparent viscosity (Table). In the author's view the hardness of the coke material and the degree of fissuring depend on the viscosity of the plastic mass of coal and, therefore, the forecasting of coke properties can be based on laboratory testing of

TITLE: On a Procedure for the Coking of Lignites (O sposobе koksovaniya burykh ugley)

PERIODICAL: Nauchnyye doklady vysshey shkoly. Khimiya i khimicheskaya tekhnologiya, 1959, Nr 1, pp 169 - 172 (USSR)

ABSTRACT: The procedures hitherto in customary use for the briquetting of powdered, dried lignite at high pressure (up to 1800 kg/cm²) and with subsequent heating to 950° in a vertical chamber furnace are not always successful as pressure and temperature do not act simultaneously. Non-caking coals and lignite yield brittle coke briquets. An attempt was made to produce coke briquets in an electrically heated mold. When a certain temperature (400-450°) had been reached, pressure was applied (300-500 kg/cm²), which was but only allowed to act for a short time, not more than for a few minutes. Afterwards the briquets were coked in muffle furnace, and the coke was tested with regard to compactness. Coal analysis data and test results of the cokes are listed in tables. The dependence on temperature and pressure of the

Card 1/2

SCV/156-55-1-44/54

On a Procedure for the Coking of Lignites

compactness is graphically represented. Thermo-briquetting yields considerably better results than do the separate actions of pressure and temperature. A coke is obtained which is equal to the ordinary metallurgical coke. This is explained by the fact that the action of pressure at the instance of a thermal reaction (splitting-off of side radicals, formation of aromatic C-lattices) results in new bonds at the contacts increased in number by the action of pressure. There are 2 figures, 1 table, and 3 references, 2 of which are Soviet.

TITLE:

On the Process of the Formation of Coke From Lignite Briquets

PERIODICAL:

Izvestiya vysshikh uchebnykh zavedeniy. Khimiya i khimicheskaya tekhnologiya, 1959, Vol 2, Nr 3, pp 454-459 (USSR)

ABSTRACT:

For their investigations the authors used lignites of different types. Coals from Kushmuranskoye and Eginsayskoye deposits of the Ubaganskiy basin were investigated more accurately. The coke briquets were produced under a pressure of 2000 kg/cm² and had a diameter of 45 mm. The humidity content of the coal was 10-12%. Prior to coking, the briquets were dried for 90 minutes at 150°. Temperature was then increased to 950° at a rate of 3° per minute. In the heating process the solidity of the briquets changes considerably. One of the most important factors causing this change is the solidification of the coal material (change of the cohesive powers). In heating up to a certain temperature the hardness of the coal is increased (Ref 2). For this reason the forming coke briquets are more solid than the initial briquets. Moreover, also the forces of interaction between the grains at the contact surfaces (change of the adhesive power) change. This change depends on the character of

Card 1/3

On the Process of the Formation of Coke From Lignite SOV/153-2-3-27/29
Briquets

the chemical transformations during heating and it is closely connected with the shrinkage of the coal particles. Distinction must be made between the shrinkage of the individual grains (λ) and the shrinkage of the entire briquet (λ'). The solidity of the coke briquet at otherwise equal conditions is the higher the higher the ratio $\frac{\lambda'}{\lambda}$. Figure 1 shows the

connection between the solidity of the coke briquet and the shrinkage of the volume for a series of coal samples. In this connection the more solid coke is obtained the more finely lignite was crushed. Table 1 shows the connection between the degree of the crushing of coal, the solidity and the one-dimensional shrinkage for various coke briquets. Also pressure exercises a considerable influence on the shrinkage of the coke briquets. This connection is shown by table 2. Shrinkage does not only depend on the coal properties but also to an important degree on the method of heating. Rapid heating accelerates the shrinkage of the individual grain (λ). By this fact the contact between the grains is disturbed and the solidity decreases due to a decrease in the shrinkage of the total briquet (λ'). The quality of coke may be improved by

Card 2/3

Briquets

carrying out the coking in two steps in order to warrant a constant contact between the individual particles. The entire complex of problems is discussed in detail in this paper. There are 2 figures, 2 tables, and 9 references, 7 of which are Soviet.

TITLE: Mechanical Strength and Polymeric Structure of Thermally
Treated Coals

PERIODICAL: Izvestiya Akademii nauk SSSR, Otdeleniye tekhnicheskikh
nauk, Metallurgiya i toplivo, 1959, Nr 3, pp 171-175(USSR)

ABSTRACT: Changes in microhardness, resistance to crushing (in a
drum containing steel balls), interlattice order and
sizes of carbon layers of solid residues obtained on
thermal decomposition of various coals in the
temperature range 500 to 2340°C were studied. A regular
relationship between the course of changes in the
mechanical strength and molecular-structural
transformations, which take place in the residues on
the temperature at which coal was treated, was
established (Fig 1, 2, 3 and 4). The microhardness
depends on the total number of spatial bonds of the
polymeric substance of the solid carbonaceous residue.
The dependence of changes in the resistance to crushing
on the temperature at which coal was treated is related

SOV/32-25-2-26/78

TITLE:

Evaluation of the Sintering Capacity of Coals With Reduced Plastic Layer (Otseňka spekayemosti ugley s ponizhennym plasticheskim sloyem)

PERIODICAL:

Zavodskaya Laboratoriya, 1959, Vol 25, Nr 2,
pp 179 - 181 (USSR)

ABSTRACT:

In the USSR bituminous coal is classed according to its volatile components and sintering capacity (expressed by the thickness of the plastic layer). On this basis the coal standards for the Donbass (GOST 8180-56), Karaganda (GOST 8150-56), Kuzbass (GOST 8162-56), Pechora (GOST 6991-54) and other coal deposits of the USSR have been established. Since thicknesses of the plastic layer below 5-6 mm cannot be determined by plastometric investigations, only a qualitative evaluation of the nonvolatile residue can be carried out with these sorts of coal. A method for the determination of the inflation coefficient B, i.e. a quantitative evaluation of the sintering capacity of coals with a minor plastic layer, has already been proposed (Ref 1). In the application

Card 1/2

Evaluation of the Sintering Capacity of Coals With
Reduced Plastic Layer

SOV/32-25-2-26/78

of this method only a light weighed sample (2 g) is needed, and the duration of analysis is short. In the present case the working principle consists of an investigation of the coke grains in a cylinder (Fig) with 50 rpm. For this purpose the material had to pass from the plastometric vessel through a sieve No 1.6 GOST 3584 - 53, and the particles remaining on the sieve were filled into the cylinder. The quotient of the volume remaining in the sieve No 1.6, after the treatment (5 min = 250 rpm) in the cylinder, and of the weighed sample serves as classification value (Table). A determination of the sub-groups of the international coal classification is investigated at present, according to the modification of the IGI-VUKhIN method. The above mentioned table contains several sorts of coal. There are 1 figure, 1 table and 2 Soviet references.

TITLE: Relationship Between Thermophysical and Mechanical
Properties of Highly Carbonized Polymeric Materials 1

PERIODICAL: Doklady Akademii nauk SSSR, 1960, Vol. 133, No. 5,
pp. 1143-1145

TEXT: The authors of this paper discuss the relationship existing
between specific thermal capacity, thermal diffusivity, heat conductivity,
microhardness, as well as resistance to comminution of solid products.
These products were obtained by thermal decomposition of fossil coals
in the temperature range up to 2350°C, and can be regarded as highly
carbonized polymers. At the same time, the authors established a
functional relationship between variations in specific heat c_p and the
magnitude of plane layers of carbon atoms. Nonsintering anthracites and
Donets gas coal, whose variations in strength had been studied previously
(Ref. 3), were examined. Proceeding from the experimental results

obtained by the determination of the specific heat and of heat conductivity as well as of the weight by volume, the authors calculated the values of the coefficient of heat conductivity. Microhardness was determined by an apparatus of the type ПМТ-2 (PMT-2) devised by M. M. Khrushchev and Ye. S. Berkovich; the resistance to comminution was established with the aid of the ¹⁸СИМС (VIMS) microdispergometer. The materials examined chiefly consisted of carbon; therefore, the variations in thermophysical and mechanical properties of highly carbonized polymers are, on the whole, related to their structural transformations. As can be seen from Figs. 1 and 2, there is a regular relationship between the specific heat and the expansion L of the plane layers of carbon atoms of highly carbonized polymers. With increasing L the number of carbon atoms deposited in single layers also rises. Consequently, the high-frequency oscillations of these atoms decrease in the range of Debye temperatures. An increase in the extension of plane layers of carbon atoms is the main cause of a drop in specific heat of highly carbonized polymers. Moreover, on a thermal decomposition of coals up to 1100°C, the chemical bonds

between carbon atoms become closer. This is in agreement with results obtained and with a sudden rise in microhardness and heat conductivity when heating the initial coals up to 1100°C (Fig. 3). When the decomposition temperature rises beyond 1100-1300°C, processes of thermal destruction of the carbon side chains and a growth in the plane layers of carbon atoms take place until the stage of graphitization. The resistance to comminution of coals depends on two factors: material hardness and plasticity. Microhardness increases in the first heating stage (Fig. 3). The material also becomes more brittle. Hence, the resistance to comminution remains fairly constant, or even drops. The results obtained make it possible to evaluate the thermal stability of highly carbonized polymers, and can be used for the production of such materials with given thermomechanical properties. There are 3 figures and 3 Soviet references.
